

Week 04: Padding, Border, & Margin

Padding, Border, and Margin in CSS

Padding

The **padding** is the space between the content of an element and its border. It creates space inside the element, pushing the content away from the border.

Padding Example

In the example above, the content is pushed away from the edges of the box by the padding. The padding is added inside the box, around the content.

Border

The **border** is the line that surrounds an element, between the padding and margin. You can adjust the border's width, style, and colour. Borders are placed outside the padding area but inside the margin area.

Border Example

In the example above, the border surrounds the padding area and separates the element from the surrounding space. You can adjust the thickness, style (solid, dashed, etc.), and colour of the border.

Margin

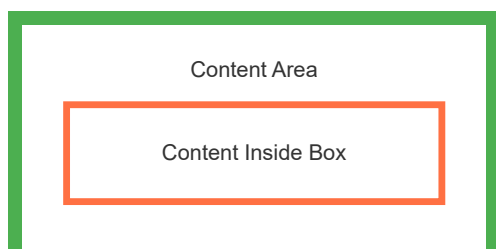

The **margin** is the space outside the element, between the element's border and other surrounding elements. The margin creates space around the element.

Margin Example

In this example, the margin creates space between the element and any other elements on the page. It's the outermost space of the box model.

How **Padding**, **Border**, and **Margin** Work Together

The following diagram will help you understand how **padding**, **border**, and **margin** work together in the CSS box model:

From the inside out:

- **Content** is the innermost part.
- **Padding** is the space between the content and the border.
- **Border** is the line that surrounds the element, between padding and margin.
- **Margin** is the outermost space between the element's border and other elements.
